ABSTRACT

This paper presents a new robust decentralized design of frequency stabilizer for superconducting magnetic energy storage (SMES) based on an \( H_{\infty} \) control. As an interconnected power system is subjected to load disturbances, system frequency may be severely disturbed and oscillate. To stabilize frequency oscillations, the active power control by SMES installed in a power system can be applied. The proposed decentralized control design translates interconnected power systems installed with SMESs into a Multi-Input Multi-Output (MIMO) control system. The technique of overlapping decompositions is applied to extract the decoupled subsystem with Single-Input Single-Output (SISO) from an MIMO system. As a result, a frequency stabilizer of SMES can be independently designed to enhance the damping of the inter-area mode embedded in the decoupled subsystem. In addition, to guarantee the robust stability of system against uncertainties such as system parameters variations etc., the multiplicative uncertainty model is also incorporated. Consequently, \( H_{\infty} \) control via a mixed sensitivity approach is applied to design the robust frequency stabilizer of SMES. Study results explicitly show that the robustness of the \( H_{\infty} \)-based frequency stabilizer of SMES is superior to that of the PID based stabilizer under various load disturbances and negative damping.

1. INTRODUCTION

Nowadays, various kinds of apparatus with large power consumption, such as, a magnetic levitation transportation, a large scale accelerator, a testing plant for nuclear fusion etc., tend to increase significantly. When these loads are concentrated in an interconnected power system, they may cause a serious problem of frequency oscillation. Especially, if the frequency of changing load is in the vicinity of the inter-area oscillation mode (0.2-0.8 Hz), the oscillation of system frequency may experience a serious stability problem due to an inadequate damping. Under this situation, the conventional frequency control, i.e. a governor, may no longer be able to absorb the large frequency oscillations due to its slow response [1]. In order to compensate these sudden load changes and stabilize frequency oscillation, an active power source with fast response, such as SMES [2], is expected as one of the most effective countermeasure.

In the literature [3-5], a SMES is proposed for investigating its application to frequency control. It has been observed that a SMES can effectively reduce frequency and tie-line power oscillations following sudden load disturbances. Nevertheless, system uncertainties such as changes in system configuration due to unpredictable disturbance, system parameters variation and modeling
errors, etc. have not been considered in these literatures. The frequency stabilizer of SMES that are designed without taking system uncertainties into consideration may not guarantee a robust stability of the system.

To solve this problem, this paper proposes a new robust decentralized design of frequency stabilizers for SMESs based on an $H_\infty$ control. The multiplicative uncertainty model is employed to represent all possible uncertainties in interconnected power systems. The $H_\infty$ control based on mixed sensitivity approach is applied to design frequency stabilizer. The robustness of designed frequency stabilizer is evaluated in the three-area loop interconnected system.

The organization of this paper is as follows. Section 2 provides the motivation of the proposed control. Next, Section 3 explains the proposed design method. Subsequently, the simulation study of designed PSSs is given in Section 4. Finally, the outcomes from this paper are summarized.

2. MOTIVATION OF THE PROPOSED CONTROL

![Three-Area Loop Interconnected Power System with SMESs](image)

Fig. 1 Three-Area Loop Interconnected Power System with SMESs

A three-area loop interconnected power system [6] as shown in Fig. 1 is used as a study system. It is assumed the large loads with sudden change have been installed in areas 1 and 3. These load changes cause severe frequency oscillations in both areas. To solve this problem, SMES1 and SMES3 are placed in areas 1 and 3 respectively. Here, the frequency stabilizer of each SMES is designed by the proposed control.

3. PROPOSED CONTROL DESIGN

3.1 Coordinated Control of SMES and Governor

The response of SMES is extremely rapid when compared to the conventional frequency control system, i.e. a governor. The difference in responses signifies that the SMES and governor can be coordinated.

When a power system is subjected to a sudden load disturbance, the SMES quickly acts to damp frequency oscillation in the transient period. Subsequently, the governor continues to eliminate the steady-state error in frequency oscillation. As the periods of operation for the SMES and governor do not overlap, the dynamic of governor can then be neglected in the design of frequency stabilizer for the sake of simplicity.
### 3.2 Linearized Power System Model

The power system shown in Fig. 1 can be represented by a linearized power system model, as shown in Fig. 2. Note that the governors are eliminated in this system. The SMES model is represented by the active power controller [7]. The dynamic characteristic of SMES is modeled as the first order controller with a time constant $T_{SM} = 0.03$ sec. The linearized state equation of Fig. 2 can be expressed as:

$$
S : \begin{bmatrix}
\Delta f_1 \\
\Delta P_{T12} \\
\Delta f_2 \\
\Delta P_{T23} \\
\Delta f_3 \\
\end{bmatrix} = \begin{bmatrix}
a_{11} & a_{12} & a_{13} & a_{14} & a_{15} \\
a_{21} & a_{22} & a_{23} & a_{24} & a_{25} \\
a_{31} & a_{32} & a_{33} & a_{34} & a_{35} \\
a_{41} & a_{42} & a_{43} & a_{44} & a_{45} \\
a_{51} & a_{52} & a_{53} & a_{54} & a_{55} \\
\end{bmatrix}
\begin{bmatrix}
\Delta f_1 \\
\Delta P_{T12} \\
\Delta f_2 \\
\Delta P_{T23} \\
\Delta f_3 \\
\end{bmatrix}
$$

$$
+ \begin{bmatrix}
b_1 & b_2 \\
b_3 & b_4 \\
b_5 & b_6 \\
\end{bmatrix}
\begin{bmatrix}
\Delta P_{SMES1} \\
\Delta P_{SMES2} \\
\end{bmatrix}
$$

Fig. 2 Linearized Model of Three Area System for Control Design

(1)
where, \( a_{11} = -D_1/M_1, a_{12} = (ar_{12} + T_{12}/T_{12})/M_1, a_{14} = -T_{13}/M_1T_{23}, a_{21} = -2\pi T_{12}, a_{23} = 2\pi T_{12}, a_{12} = -1/M_2, a_{33} = -D_2/M_2, a_{44} = -ar_{23}/M_2, a_{45} = 2\pi T_{23}, a_{54} = -a_{23}/M_1, a_{55} = (1+ar_{13}T_{13}/T_{23})/M_3, a_{35} = -D_3/M_3, \\
\)
\( b_{11} = -1/M_1, b_{32} = -1/M_2, \) the others are equal to 0

The variable \( \Delta P_{T_{31}} \) is represented in terms of \( \Delta P_{T_{12}} \) and \( \Delta P_{T_{23}} \) by

\[
\Delta P_{T_{31}} = -\frac{T_{31}}{T_{12}}\Delta P_{T_{12}} + \frac{T_{31}}{T_{23}}\Delta P_{T_{23}} \tag{2}
\]

Thus, \( \Delta P_{T_{31}} \) has disappeared in Eq. (1). This system has two conjugate pairs of complex eigenvalues and a negative real eigenvalue. The former corresponds to two inter-area oscillation modes and the latter the inertia center mode. Based on the mode controllability matrix, the inter-area modes between areas 1 and 2, and areas 2 and 3 are controllable for the control inputs \( \Delta P_{\text{AES1}} \) and \( \Delta P_{\text{AES3}} \), respectively. Accordingly, the design purpose of frequency stabilizer is to enhance the damping of the mentioned inter-area modes.

### 3.3 Overlapping Decomposition

Since the system (1) is a Multi-Input Multi-Output (MIMO) system, it is not easy to design both frequency stabilizers simultaneously and directly from the system. To simplify the design process, the technique of overlapping decompositions [8-9] is applied to reduce the system (1) to a subsystem embedded with only the inter-area mode of interest. The original system (1) is referred to as the system \( S \).

\[
S : \begin{bmatrix}
\dot{x}_1 \\
\dot{x}_2 \\
\dot{x}_3 \\
\end{bmatrix} = \begin{bmatrix}
A_{11} & A_{12} & A_{13} \\
A_{21} & A_{22} & A_{23} \\
A_{31} & A_{32} & A_{33}
\end{bmatrix} \begin{bmatrix}
x_1 \\
x_2 \\
x_3
\end{bmatrix} + \begin{bmatrix}
B_{11} & B_{12} \\
B_{21} & B_{22} \\
B_{31} & B_{32}
\end{bmatrix} \begin{bmatrix}
u_1 \\
u_2
\end{bmatrix} \tag{3}
\]

The sub-matrices \( A_{ij} \) and \( B_{ij}, \ (i, j = 1, 2, 3) \) have appropriate dimensions identical to the corresponding states and input vectors. According to the process of overlapping decompositions, the system \( \tilde{S} \) can be expressed as:

\[
\tilde{S} : \begin{bmatrix}
\dot{z}_1 \\
\dot{z}_2 \\
\end{bmatrix} = \begin{bmatrix}
A_{11} & A_{12} & 0 & A_{13} \\
A_{21} & A_{22} & 0 & A_{23} \\
A_{31} & 0 & A_{32} & A_{33}
\end{bmatrix} \begin{bmatrix}
z_1 \\
z_2 \\
\end{bmatrix} + \begin{bmatrix}
B_{11} \\
B_{21} \\
B_{31}
\end{bmatrix} \begin{bmatrix}
u_1 \\
u_2
\end{bmatrix} \tag{4}
\]
where $z_1 = \begin{bmatrix} x_1' \\ x_2' \end{bmatrix}$ and $z_2 = \begin{bmatrix} x_1'' \\ x_2'' \end{bmatrix}$. Subsequently, the system $\dot{S}$ can be decomposed into two interconnected overlapping subsystems, i.e.

\[
\dot{S}_1 : \dot{z}_1 = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} z_1 + \begin{bmatrix} B_{11} \\ B_{21} \end{bmatrix} u_1 + \begin{bmatrix} 0 \\ 0 \end{bmatrix} z_2 + \begin{bmatrix} B_{12} \\ B_{22} \end{bmatrix} u_2
\]

(5)

\[
\dot{S}_2 : \dot{z}_2 = \begin{bmatrix} A_{22} & A_{23} \\ A_{32} & A_{33} \end{bmatrix} z_2 + \begin{bmatrix} B_{21} \\ B_{23} \end{bmatrix} u_2 + \begin{bmatrix} A_{11} \\ A_{31} \end{bmatrix} z_1 + \begin{bmatrix} B_{31} \\ B_{32} \end{bmatrix} u_1
\]

(6)

and

The state variable $x_2$ is repeatedly included in both subsystems, which implies “Overlapping Decompositions”.

For system stabilization, two interconnected subsystems $\dot{S}_1$ and $\dot{S}_2$ are considered. The terms in the right hand sides of Eqs. (5) and (6) can be separated into the decoupled subsystems (as indicated in the parenthesis in Eqs. (5) and (6)) and the interconnected subsystems. As mentioned in [8-9], if each decoupled subsystem can be stabilized by its own input, the asymptotic stability of the interconnected overlapping subsystem and are maintained. Moreover, the asymptotic stability of the original system is also guaranteed. Consequently, the interactions of the decoupled subsystems with the interconnection subsystems in Eqs. (5) and (6) are regarded as perturbations. They can be neglected during control design. As a result, the decoupled subsystems of Eqs. (5) and (6) can be expressed as:

\[
\dot{S}_{d1} : \dot{z}_1 = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} z_1 + \begin{bmatrix} B_{11} \\ B_{21} \end{bmatrix} u_1
\]

(7)

and

\[
\dot{S}_{d2} : \dot{z}_2 = \begin{bmatrix} A_{22} & A_{23} \\ A_{32} & A_{33} \end{bmatrix} z_2 + \begin{bmatrix} B_{22} \\ B_{32} \end{bmatrix} u_2
\]

(8)

By regarding the power deviation between areas 1 and 2 ($\Delta P_{t12}$) as the overlapped variable for design of frequency stabilizer of SMES1, the subsystem embedded with the inter-area mode between areas 1 and 2 can be expressed as:

\[
\dot{G}_m : \begin{bmatrix} \Delta f_1 \\ \Delta P_{t12} \end{bmatrix} = \begin{bmatrix} -D_1/M_1 \\ -2\pi T_1 \\ -D_2/M_1 \\ -2\pi T_2 \end{bmatrix} \begin{bmatrix} \Delta f_1 \\ \Delta P_{t12} \end{bmatrix} + \begin{bmatrix} 1/M_1 \\ 0 \end{bmatrix} \Delta P_{\text{smes1}}
\]

(9)
Next, by considering the power deviation between areas 2 and 3 \( (\Delta P_{T23}) \) as the overlapped variable for design of frequency stabilizer of SMES3, the subsystem embedded with the inter-area mode between areas 2 and 3 can be expressed as:

\[
\begin{bmatrix}
\Delta P_{T23} \\
\Delta f_3
\end{bmatrix} = \begin{bmatrix}
0 & -2\pi T_{23} \\
1 + a_1 T_{23} / M_1 / M_2 & -D_1 / M_1
\end{bmatrix} \begin{bmatrix}
\Delta P_{T23} \\
\Delta f_3
\end{bmatrix} + \begin{bmatrix}
0 \\
-1 / M_1
\end{bmatrix} \Delta P_{SMES3}
\]

\( (10) \)

Eqs. (9) and (10) are used to design SMES1 and SMES3, respectively. It should be noted that after the process of overlapping decompositions, the original MIMO system (1) is divided into two decoupled Single-Input Single-Output (SISO) subsystems (Eqs. (10) and (11)). Accordingly, each frequency stabilizer can be independently designed in the decoupled subsystem.

### 3.4 \( H_\infty \) Control Design

![Diagram of \( H_\infty \) control design](image)

In order to design the controller based on \( H_\infty \) method, each decoupled subsystem can be formulated into Linear Fractional Transformation model in Fig. 3 (10). The multifacutative uncertainty is used to model all possible perturbed plants. For the system notations, \( P \) is the interconnected system which consists of nominal plant \( G \), i.e., a transfer function of a decoupled subsystem, performance weighting function \( W_s \) and uncertainties weighting function \( W_{r,y} \) is a measurement plant output, \( u \) is a control signal, \( w_i \) and \( w_o \) are disturbances at plant input and output, respectively, \( z_i \) and \( z_o \) are error signals of \( W_f \) and \( W_s \) weights, respectively. The \( H_\infty \) controller is represented by controller \( K \). It utilizes the frequency deviation \( \Delta f_o \) of the controlled area as the feedback signal input.

To achieve robustness, the controller must be obtained satisfying inequality (11) and (12) for the control system

\[
\| P \|_\infty \leq \| W_s^{-1} \|_\infty \tag{11}
\]

\[
\| P \|_\infty \leq \| W_T^{-1} \|_\infty \tag{12}
\]

where, \( S \) is the sensitivity transfer function \((I + G K)^{-1}\) and \( T \) is the complementary sensitivity transfer function \((G K (I + G K)^{-1})\). According to inequalities (11) and (12), The \( W_s \) is selected in form of low pass filter as:
\[ W_s = \frac{s+5}{2s+5} \] (13)

For all frequencies, the relation of \( S + T = I \) is held. Thus, \( W_T \) is selected in form of high pass filter as:

\[ W_T = \frac{s+3}{s+10} \] (14)

As a result, the \( H_- \)-based frequency stabilizer of SMES in an area 1 is

\[ K_{SMES\;1} = \frac{34s^3 + 781s^2 + 1379s - 157}{s^4 + 129s^3 + 1279s^2 + 2473s + 159} \] (15)

Fig. 4 Bode Plot of S and \( W_s^{-1} \)

Fig. 5 Bode Plot of T and \( W_T^{-1} \)
Fig. 6 Bode Plot of subsystem (9) (Before and After Applying $H_\infty$ SMES)

Fig. 4 and Fig. 5 confirm that the conditions in inequalities (11) and (12) are satisfied by the designed controller $K_{\text{SMES}_1}$. In addition, the control effect of $H_\infty$-based stabilizer is clearly shown by bode plots of designed model in Fig. 6. The $H_\infty$-based stabilizer is capable of reducing the peak resonance in the frequency of inter-area oscillation mode.

The same strategy is used to design the $H_\infty$-based stabilizer in area 3. $W_S$ and $W_T$ are selected as:

$$w_s = \frac{s+10}{2s+20}$$

$$w_T = \frac{s+4}{s+10}$$

As a result, the $H_\infty$-based frequency stabilizer of SMES in area 3 is given by:

$$K_{\text{SMES}_3} = \frac{19353^2 + 38005^2 + 13869s - 842}{s^4 + 422s^3 + 5586s^2 + 17645s + 678}$$

4. SIMULATION RESULTS

In simulation, the designed $H_\infty$-based stabilizer is compared to the PID-based frequency stabilizer. Based on the same first overshoot of frequency oscillation against 0.01 pu MW step load increase in areas 1 and 3, The PID-based stabilizer are given as:

$$K_{\text{SMES}_1} = 0.07 + \frac{1}{s} + 0.05s$$

$$K_{\text{SMES}_3} = 0.15 + \frac{1}{s} + 0.10s$$

In addition, the governor is included in a linearized power model in a simulation study, as shown in Fig. 7.
Simulation studies are separated to 3 cases as shown in Fig. 8.

Figs. 9 and 10 show the dynamics responses for 0.01 pu MW step load disturbance in areas 1 and 3. $H_\infty$-based stabilizers provide better damping effects on frequency oscillations $\Delta f_1$ and $\Delta f_3$ than those of PID-based stabilizers.
Fig. 10 Frequency Deviation of Area 3

Fig. 11 The active power output of $H_\infty$ - based stabilizer

Fig. 12 The energy deviations of $H_\infty$ - based stabilizer

Fig. 11 shows the active power outputs of $H_\infty$ - based stabilizers. The MW capacities of SMES are evaluated from the peak value of power output of the SMES. The MW capacities of SMES1 and SMES3 are 0.0044 and 0.0062 pu.MW, respectively. Fig. 12 shows the MJ energy deviations of $H_\infty$ - based stabilizers that evaluated from
\[ \Delta E_{SMES} = \int \Delta P_{SMES} \, dt \]  

(21)

Necessary MJ capacity of SMES can be calculated by:

\[ MJ \text{ Capacity} = \Delta E_{SMES(MAX)} - \Delta E_{SMES(MIN)} \]  

(22)

As a result, MJ capacities of SMES1 and SMES3 are 0.0261 and 0.0265 pu. MJ, respectively.

Next, the load changes applied to areas 1 and 3 are assumed to be \( \Delta P_{1,2} = -0.002 \sin(3t) + 0.004 \sin(6t) - 0.007 \sin(9t) \) and \( \Delta P_{1,3} = -0.001 \sin(t) + 0.004 \sin(5t) - 0.005 \sin(7t) \), respectively. Suppose that the system is in unstable state so that the system damping coefficient \( D_1 \) and \( D_2 \) are -0.3 [pu.MW/Hz]. As shown in Figs. 13 and 14, the power system with PID-based stabilizer completely loses stability, frequency oscillations in areas 1 and 3 severely fluctuate and finally diverge. On the other hand, frequency oscillations are effectively stabilized by \( H_\infty \)-based stabilizers. These results confirm that the robustness of the \( H_\infty \)-based stabilizer is superior to that of the PID-based stabilizer.

Fig. 13 Frequency Deviation of Area 1

Fig. 14 Frequency Deviation of Area 3
5. CONCLUSIONS

This paper focuses on the new robust design of frequency stabilizer of SMES by taking system uncertainties into consideration. The overlapping decompositions technique is used to extract the SISO subsystem embedded with the inter-area oscillation mode of interest from the original MIMO system. As a result, each frequency stabilizer can be independently designed in the decoupled subsystem. By including the multiplicative uncertainty model in the decoupled subsystem, the $H_{\infty}$ control via mixed sensitivity approach can be applied to design frequency stabilizer of SMES. The resulted $H_{\infty}$ frequency stabilizer is low order controller. In addition, it used only a frequency deviation of the control area as a local signal input. Experimental studies have confirmed the high robustness of the designed frequency stabilizers against various load disturbances with changing frequency in the vicinity of inter-area mode and negative damping.
